

Chubbs Problem Statement

Build an autonomous, continuously running research agent system that:

- Monitors and extracts data from a diverse set of global web sources on an ongoing basis — e.g., public health bulletins and outbreak reports, scientific and pre-print literature, meteorological and seismic monitoring feeds, government and regulatory disaster advisories, shipping/trade/supply-chain disruption signals, and credible news and open-source intelligence.
- Synthesize these signals across sources and geographies to identify emerging patterns consistent with a pandemic, natural catastrophe, or other high-impact global event well before the event becomes mainstream headline news.
- Assesses and scores the likely severity, geographic spread, and time horizon of the detected event, with a clear, auditable rationale for how the system arrived at that assessment.
- Translates the detected event into distinct, audience-specific impact briefs covering three lenses: Health impact (who is exposed, projected strain on health systems), Wealth impact (markets, sectors, and asset classes likely affected), and Insurance impact (lines of business, claims exposure, and reserving implications likely affected).
- Notifies the right audience individuals, institutions (insurers, health systems, financial institutions), or the public through a clear, timely, and appropriately caveated alert.

Teams have full latitude in choosing which real-world event categories to prioritize (disease outbreak signals, climate/weather catastrophe, seismic activity, geopolitical/supply-chain shocks, etc.) and which web sources to target — but the system's agent architecture, reasoning quality, and notification design are what will be evaluated most closely.
